

AI Support Tool for Women Balancing Work, Caregiving, and Well Being

Week 1 : Define structured input schema and user-flow [see CARE-GEN's structure/process]. Build a very simple input form and rule-based recommendation prototype. Seek early feedback from Dr Bazzano and team.

Week 2 : Integrate LLM-based response generation conditioned on structured inputs. Deploy a working minimal web interface that has a calibrated backend (Flask/FastAPI words; Django is overkill but recommended for deployment-at-scale).

Week 3 : Design personalization layer using simple scoring (binary assessment, analytical, etc) or use lightweight ML model (o-llama might work well).

Week 4 : Collect small internal test dataset and refine output quality. Documentation becomes the bulk of the work here to compile current and past objectives.

Week 5 : Add contextual memory or session persistence (this could take a while to perfect). Improve recommendation logic.

Week 6 : Conduct user testing with feedback collection. Refine UX and response framing. *Project optimization for general-public use ramps up here.*

Week 7 : Implement safety filters and constraints to prevent harmful or misleading advice.

Week 8 : Continue week 7's objective alongside optimizing performance and clean up architecture.

Week 9 : Finalize prototype, prepare demo and structured plan for validation study or clinical collaboration.
